# Chapter 1

## TomPiler

Version

0.2.5

### 1.0.1 Useful Pages

- [compfiles.h](#)
- [file\\_util.h](#)
- [dfa.h](#)
- [tokens.h](#)
- [scan.h](#)
- [TCompFiles](#)
- [Scanner](#)

### 1.0.2 About

Created by Group 3 for CSC-460, Language Translations with Dr. Pyzdrowski, at PennWest California.

## Chapter 2

# changelog

2/15/2023: Karl and Thomas

- Better printing for compfiles opening and closing and better print formatting.
- Negative intliterals on dfa.
- [Tompiler.h](#)
- Brought back the expanding buffer! Using it for actual token strings now instead of an entire line.
- Brought in [terminal.h](#) for virtual terminal color sequences and ported it to C.
- Pretty printing for Hello and Goodbye.

2/15/2023: Karl

- Finished debugging full DFA.
- Rewrote scanner in [scan.h](#). No more using memory allocation and [TokenCatch](#) structures. It reads from file and writes directly to the listing and output files now.
- Deleted scanner.c, scanner.h, scanner\_util.c, scanner\_util.h and associated test files.
- Deleted the recognize keyword token function and the associated dfa, since the new dfa covers everything.
- If we need those files and features back, we can revert to an earlier commit.

2/14/2023: Karl

- Created a FULL dfa planned to replace all current logic.
- Moved all test header files to one header file "test.h".

2/13/2023: Karl and thomas

- fixed listing file not loading
- fixed extractInt AND extractInt tests (they were using extractWord)!
- running error count and print errors

- fixed detect SCANEOF
- fixed null terminates at end of buffer for no overflow print
- fixed last line being ignored
- several types of token catch initializers
- token catch allocates memory; can use the tokens later in the parser
- scanner printLine fixes
- print error count
- Token\_GetOpRaw
- formatting line printing

2/13/2023: All Group Members

- Extract op
- Fleshed out the switch statement for take Action
- printLine always happens at the end of populateBuffer now
- extractOperator and Scanner\_ExtractOperator.... extractOperator is in [Scanner](#) not scanner\_util because it is dependent
- Token\_CatchOp Token\_CatchError

2/12/2023: Karl

- Added recognizers for trueop, nullop, falseop to the state transition table, which I had missed before.
- Skipwhitespace now returns the number of characters missed. This can be useful if we extract a number and it isn't followed by a whitespace (skipwhitespace will produce 0.) This may be a cause for an error print. (Worth asking)
- Fixed extractWord errors and added Scanner\_ExtractWord
- Added extractInteger and Scanner\_ExtractInteger
- Added a boundaries member to Tscanner. This is a list of all boundry characters that delimit words, identifiers, and number and it includes all operators plus whitespace and EOF. See [Scanner\\_Init\(\)](#) for how it's constructed.
- Token Recognize now returns ERROR if there is a non number, non alphanumeric within the tested string. It also now allows for identifiers to have numbers.
- Created Token wrapping struct called [TokenCatch](#) that encapsulates info about the token such as the recognized raw string, line number, and so forth.
- [Scanner](#) now takes files on Scanner\_Scan(files...) not on [Scanner\\_Init\(\)](#)
- Init and Delnit functions in main
- Moved switch statement/dispatcher into a function Scanner\_TakeAction(lookaheadResult)
- Made basic Scanner\_Scan(); currently will print the listing file numbers and lines only

2/11/2023: Karl

- Added skipWhitespace general function in scanner\_util and added tests for it
- Added charIn function in scanner\_util which is used by extractWord function in scanner\_util.

2/10/2023: Karl

- Added Scanner\_populateBuffer() and tested it.
- Created Scanner\_LookAhead() and put a switch statement in Scanner\_Scan()

2/8/2023: Karl, Thomas, Anthony

- created scanner.h and scanner.c
- add struct to hold scanner info
- scanner lifecycle functions
- scanner buffer functions
- scanner\_util , created buffer resize and refresh functions
- created tests for scanner\_util

2/7/2023: Karl

- abstracted command line argument parse and calls to a new function, CompFiles\_FileOpenFromCLIArgs, which also generates the Temp file.
- created Tokens\_GetName, the tokens Map, the tokens enum.
- created a state transition table as a 3d array for a keyword recognizer Token\_RecognizeKeyword. Used excel to design the table; .xlsx is in the /docs folder.

2/1/2023 : All Group Members

- used fileapi.h to create a getAbsolutePath function
- created checkIfSamePaths function to compare file name actual paths
- reworked the validate files functions to check for output/input name collisions
- adjusted some printing
- fixed tempfile bug

1/28/2023: Karl

- used doxygen to generate documentation

1/27/2023: Thomas, Karl

- wrote copy inputs to outputs function

1/26/2023 : All group members

- refactored file\_util into two files: compfiles and file\_util
- worked on logic for validating an output file name
- auto-generate temp file
- validate listing file in a similar way to output file
- combined validation functions into one validate func; just pass it the command line arguments

1/25/2023 : Thomas

- promptOutputFile()
- Modified [getString\(\)](#) to use realloc

1/24/2023 : All group members

- worked on main logic
- changed CompFiles struct to be a state machine
- created promptFilename

1/23/2023 : Thomas and klm127

- changed Author comment to include e-mail and class name.
- removed old addExtension function, old promptFilename function, and closeFile function.
- added promptFilename and getString function(not yet covered by unit tests)
- removed all of the stdin swapping to a [separate repo](#), and tested it, due to nagging bugs.
  - NOTE: It turned out that the bug was that [dup2](#) closes a file and `fclose` was being called afterwards.

moved test dependencies to a sub folder `lib` and updated compilation commands to use this on the include path

1/22/2023 : thomas and klm127

- added removeExtension function and tests
- confirmed getchar will read an 'enter'.
- thomas fixed prompting function to accept alternate inputs
- added backupFile function and tests
- Included tests for filepaths with directories
- redid filenameHasExtension. It now allows for filenames like ".bob" and doesnt allow filenames that end in slashes. It does allow folders to have '.'s in them.

1/21/2023 : klm127

- added `#pragma` region directives to header files. This is basically just markup for VSCode. Each of these regions can now be folded in Visual Studio or VSCode. This does not affect -ansi compilation on MinGW-↔ W64 gcc; as far as I can tell. The purpose is to make the code much easier to navigate without relying on tab-based folding. [See Also: stackoverflow answer](#)

- Cleaned up comments, tab-based folding, etc.
- Fixed up the `addExtension` to use `malloc` to create a longer, concatenated string out of its inputs. Added unit tests for `addExtension`.
- Refactored std swapping test utility functions. The best way to test a prompter is now to use is to call `setSTDin3`, get the value, then dont forget to call `restoreSTD3()` *before* making a test-based assertion.

1/20/2023 : All group members in collaboration

- created `promptUserOverwriteSelection`.
- created tests for `promptUserOverwriteSelection`. This was quite an involved task because we had to figure out how to temporarily replace `stdin` and `stdout` with alternative files so that we could test functionalities like `scanf`. Ultimately we were able to figure it out.

1/19/2023 : klm127

- changed directory structure, added docs, src, and tests
- created changelog, included CuTest's readme in the docs
- updated `tasks.json` in `.vscode` to configure code generation
- output file is now `fileopen.exe` due to interpretation of video instructions
- added `.gitignore` so we can exclude executables from github
- Added the testing suite CuTest. More info [here](#)
- Added the functions `fileExists` and `filenameHasExtension`
- Added unit tests for `fileExists` and `filenameHasExtension`

## Chapter 3

# VSCode setup instructions

VSCode provides a decent environment to work in C with its highly customizable features, low overhead, and rich extension options.

The folder `.vscode` configures the workspace for use with VSCode.

`tasks.json` describes build and run commands.

Ctrl+Shift+B will build and run the programs.

You may have to change `compilerPath` in `c_cpp_properties.json` to your own compiler.

I'm using GCC 8.1 (came with CodeBlocks) with the `-ansi` flag.

I referenced this article when setting up the VSCode environment. [Medium Article](#)

I referenced the [gcc documentation](#) while setting up the compiler.

## Chapter 4

# Tompiler Readme

Tompiler will be a relatively simple compiler built for educational and explorative purposes.

### 4.1 Compiling

Compiler configurations are stored in the .bat files. There are two of them.

- `runTests.bat` compiles and runs the tests.
- `compile.bat` compiles and runs the code.

### 4.2 Using

Running `compile.bat` will run the compiler after executing. You can also find the executable, `fileopen.exe`, in your `bin` directory.

It takes up to two command line arguments. The first argument can be an input file path while the second argument can be an output file path.

Place the `bin` directory on your system path if you want to be able to run tompiler from anywhere.

### 4.3 Folder and file Descriptions

- `.vscode` : Contains vscode configurations.
- `docs` : Contains additional documentation
- `src` : Contains source code
  - `main.c` : Program entry point
  - `compfiles.c / .h` : struct for managing input output file access
  - `file_util.c / .h` : file i/o helpers for the compiler
  - `dfa.c / .h` : The DFA which drives the scanning process.

- 
- tests : Contains source code for tests
  - lib: Contains test dependencies
    - \* CuTest.c / .h : CuTest micro test framework
    - \* std\_swapper.c / .h : For swapping stdin and out with files.
  - file\_util\_test.c : tests for file util
  - dfa\_test.c : tests for dfa.
  - tokens\_test.c : test for token functions.
  - main\_test.c : entry point for test compilation
  - tests.h : each test file has one exported member, a function that returns the testing suite. They are all declared here.

## 4.4 Included 3rd party library, CuTest.

[Link to Ctest page](#)

This is a small bit of code (only 340 lines!) that provides a unit testing skeleton.

## 4.5 Credits

- Tom Terhune
- Karl Miller
- Anthony Stepich

## Chapter 5

# Data Structure Index

### 5.1 Data Structures

Here are the data structures with brief descriptions:

<a href="#">Scanner</a> . . . . .	17
<a href="#">TCompFiles</a>	
Manages input and output files . . . . .	19
<a href="#">TokenCatch</a> . . . . .	21

## Chapter 6

# File Index

### 6.1 File List

Here is a list of all files with brief descriptions:

src/ <a href="#">compfiles.c</a>	23
src/ <a href="#">compfiles.h</a>	
CompFiles struct and "methods" definitions	29
src/ <a href="#">dfa.c</a>	
The DFA and related logic definitions	37
src/ <a href="#">dfa.h</a>	
The DFA and related logic declarations	43
src/ <a href="#">file_util.c</a>	45
src/ <a href="#">file_util.h</a>	
Functions to assist with file operations	49
src/ <a href="#">main.c</a>	
Program entry point	55
src/ <a href="#">scan.c</a>	
Scanner struct and 'methods' definitions	56
src/ <a href="#">scan.h</a>	
Scanner struct and 'methods' declarations	59
src/ <a href="#">terminal.h</a>	
Windows Terminal Macros	65
src/ <a href="#">tokens.c</a>	
Token map and related functions	70
src/ <a href="#">tokens.h</a>	
Token functions declarations	73
src/ <a href="#">tompiler.c</a>	77
src/ <a href="#">tompiler.h</a>	78

## Chapter 7

# Data Structure Documentation

### 7.1 Scanner Struct Reference

```
#include <scan.h>
```

#### Data Fields

- int [line\\_no](#)
- int [col\\_no](#)
- int [errors](#)
- char \* [buffer](#)
- int [capacity](#)
- int [l\\_buffer](#)
- FILE \* [in](#)
- FILE \* [out](#)
- FILE \* [temp](#)
- FILE \* [listing](#)

#### 7.1.1 Detailed Description

[Scanner](#) struct holds references to the files being read and keeps track of the line and column position. It is a singleton.

#### 7.1.2 Field Documentation

##### 7.1.2.1 buffer

```
char* buffer
```

#### 7.1.2.2 capacity

```
int capacity
```

#### 7.1.2.3 col\_no

```
int col_no
```

The column number.

#### 7.1.2.4 errors

```
int errors
```

The error count.

#### 7.1.2.5 in

```
FILE* in
```

#### 7.1.2.6 l\_buffer

```
int l_buffer
```

#### 7.1.2.7 line\_no

```
int line_no
```

The line number being scanned.

#### 7.1.2.8 listing

```
FILE* listing
```

#### 7.1.2.9 out

```
FILE* out
```

### 7.1.2.10 temp

```
FILE* temp
```

The documentation for this struct was generated from the following file:

- [src/scan.h](#)

## 7.2 TCompFiles Struct Reference

Manages input and output files.

```
#include <compfiles.h>
```

### Data Fields

- FILE \* [in](#)
- FILE \* [out](#)
- FILE \* [temp](#)
- FILE \* [listing](#)
- short [input\\_file\\_state](#)
- short [output\\_file\\_state](#)
- short [listing\\_file\\_state](#)
- short [terminate\\_requested](#)
- short [has\\_requested\\_default\\_filename](#)
- char \* [input\\_file\\_name](#)
- char \* [output\\_file\\_name](#)
- char \* [listing\\_file\\_name](#)
- char \* [temp\\_file\\_name](#)

### 7.2.1 Detailed Description

Manages input and output files.

CompFiles is a globally accesible struct which maintains references to the loaded files.

It has a number of functions closely associated to it. In that way it is a class-like, but a singleton. There is only one CompFiles that ever should exist.

### 7.2.2 Field Documentation

#### 7.2.2.1 has\_requested\_default\_filename

```
short has_requested_default_filename
```

1 indicates that a user has requested to use a default ouput filename already. This is so that if the user selects this twice, they will automatically exit instead of looping the prompt.

#### 7.2.2.2 in

```
FILE* in
```

A file pointer to an open input file.

#### 7.2.2.3 input\_file\_name

```
char* input_file_name
```

The input filename.

#### 7.2.2.4 input\_file\_state

```
short input_file_state
```

Determines the status of input file validation.

#### 7.2.2.5 listing

```
FILE* listing
```

A file pointer to an open listing file.

#### 7.2.2.6 listing\_file\_name

```
char* listing_file_name
```

The listing filename

#### 7.2.2.7 listing\_file\_state

```
short listing_file_state
```

Determines the status of listing file validation.

#### 7.2.2.8 out

```
FILE* out
```

A file pointer to an open output file.

#### 7.2.2.9 output\_file\_name

```
char* output_file_name
```

The output filename,

#### 7.2.2.10 output\_file\_state

```
short output_file_state
```

Determines the status of output file validation.

#### 7.2.2.11 temp

```
FILE* temp
```

A file pointer to an open tmp file.

#### 7.2.2.12 temp\_file\_name

```
char* temp_file_name
```

The temp filename

#### 7.2.2.13 terminate\_requested

```
short terminate_requested
```

1 indicates that a user requested to terminate the program.

The documentation for this struct was generated from the following file:

- [src/compfiles.h](#)

## 7.3 TokenCatch Struct Reference

```
#include <tokens.h>
```

### Data Fields

- short [token](#)
- char \* [raw](#)
- int [line\\_no](#)
- int [col\\_no](#)

### 7.3.1 Detailed Description

**7.3.1.1 Note:** TokenCatch is no longer used. It was used in an earlier version of this program. It may be revived in the future depending on the needs of the parser.

### 7.3.2 Field Documentation

**7.3.2.1 col\_no**

```
int col_no
```

**7.3.2.2 line\_no**

```
int line_no
```

**7.3.2.3 raw**

```
char* raw
```

**7.3.2.4 token**

```
short token
```

The documentation for this struct was generated from the following file:

- [src/tokens.h](#)

## Chapter 8

# File Documentation

### 8.1 docs/changelog.md File Reference

### 8.2 docs/VSCode.md File Reference

### 8.3 Readme.md File Reference

### 8.4 src/compfiles.c File Reference

- short [CompFiles\\_promptUserOverwriteSelection](#) ()

#### 8.4.1 Function Documentation

##### 8.4.1.1 [CompFiles\\_AcquireValidatedFiles\(\)](#)

```
short CompFiles_AcquireValidatedFiles (  
    char * inputFilename,  
    const char * outputFilename )
```

Loops and prompts until all input and output files are set correctly or until terminate is requested. After the input, output, and listing files are generated, `CompFiles_AcquireValidatedFiles` also generates a temp file.

## Parameters

<i>inputFilename</i>	a filename with which to begin input validation with or NULL
<i>outputFilename</i>	a filename with which to begin output validation with or NULL

## Returns

1 if terminate was requested. Otherwise, 0.

## Author

klm127

## Date

1/26/2023

#### 8.4.1.2 CompFiles\_AcquireValidatedInputFile()

```
short CompFiles_AcquireValidatedInputFile (  
    char * filename )
```

Validates an input file name and sets the value in the struct. It will continue looping until the user has supplied a valid filename or elected to quit the program.

## Parameters

<i>filename</i>	a filename with which to begin input validation with or NULL
-----------------	--

## Returns

0 if the input file was validated and loaded into the struct. 1 if the user requested to terminate the program.

#### 8.4.1.3 CompFiles\_AcquireValidatedListingFile()

```
short CompFiles_AcquireValidatedListingFile (  
    const char * filename )
```

Validates a listing file name and sets the value in the struct.

Called by `CompFiles_ValidateOutputFile` after an output file has been fully validated. The parameter passed will be the name of the output file with the extension 'list' instead.

If this file happens to exist, a similar loop will occur as when a user attempts to load an extant output file. The user will be prompted to enter a new file until one is validated or they elect to exit the program.

## Parameters

<i>filename</i>	a filename with which to begin input validation with or NULL
-----------------	--

## Returns

0 if an output file was validated and loaded into the struct. 1 if the user requested to terminate the program.

#### 8.4.1.4 CompFiles\_AcquireValidatedOutputFile()

```
short CompFiles_AcquireValidatedOutputFile (  

```

```
const char * filename )
```

Validates an output file name and sets the value in the struct. It will continue looping until the user has supplied a valid filename or elected to quit the program.

#### Parameters

<i>filename</i>	a filename with which to begin input validation with or NULL
-----------------	--

#### Returns

0 if an output file was validated and loaded into the struct. 1 if the user requested to terminate the program.

#### 8.4.1.5 CompFiles\_CopyInputToOutputs()

```
void CompFiles_CopyInputToOutputs ( )
```

CompFiles\_CopyInputToOutputs copies all the data from the input file to each of the output files. After execution, all output files (tmp, list, and out) will have text identical to the input files.

#### Warning

Precondition: All CompFiles file pointers must be open and ready to read/write.

#### Author

Thomas, Karl

#### Date

1/27/2023

#### 8.4.1.6 CompFiles\_DeInit()

```
void CompFiles_DeInit ( )
```

Closes any open files and returns CompFiles to the default values. Deletes the temp file.

#### 8.4.1.7 CompFiles\_GenerateTempFile()

```
void CompFiles_GenerateTempFile ( )
```

Generates a temporary file with a unique name. This file will be destroyed when [CompFiles\\_DeInit\(\)](#) is called.

#### Author

klm127

#### Date

1/26/2023

#### 8.4.1.8 CompFiles\_GetFiles()

```
TCompFiles * CompFiles_GetFiles ( )
```

Gets the CompFiles struct so that the validated files can be used elsewhere in the program.

#### Returns

A [TCompFiles](#) struct.

#### 8.4.1.9 CompFiles\_Init()

```
void CompFiles_Init ( )
```

Initializes CompFiles struct to default values.

##### Note

Covered by unit tests.

#### 8.4.1.10 CompFiles\_LoadInputFile()

```
void CompFiles_LoadInputFile (
    FILE * newInputFile )
```

CompFiles\_LoadInputFile loads a new file pointer as the input file. If there is a file already loaded, it closes that file first.

##### Parameters

<i>newInputFile</i>	A pointer to an open file in read mode.
---------------------	---

#### 8.4.1.11 CompFiles\_LoadListingFile()

```
void CompFiles_LoadListingFile (
    FILE * newListingFile )
```

CompFiles\_LoadListingFile loads a new file pointer as the listing file. If there is a file already loaded, it closes that file first.

##### Parameters

<i>newOutputFile</i>	A pointer to an open file in write mode.
----------------------	--

#### 8.4.1.12 CompFiles\_LoadOutputFile()

```
void CompFiles_LoadOutputFile (
    FILE * newOutputFile )
```

CompFiles\_LoadOutputFile loads a new file pointer as the output file. If there is a file already loaded, it closes that file first.

##### Parameters

<i>newOutputFile</i>	A pointer to an open file in write mode.
----------------------	--

#### 8.4.1.13 CompFiles\_LoadTempFile()

```
void CompFiles_LoadTempFile (
    FILE * newTempFile )
```

CompFiles\_LoadTempFile loads a new file pointer as the temp file. If there is a file already loaded, it closes that file first.

##### Parameters

<i>newOutputFile</i>	A pointer to an open file in write mode.
----------------------	--

#### 8.4.1.14 CompFiles\_Open()

```
short CompFiles_Open (
    int argc,
    char * argv[] )
```

Parses the command line args and calls functions to acquire validated filenames.

##### Parameters

<i>argc</i>	The argument count.
<i>argv</i>	The argument array.

##### Returns

1 if terminate was requested. Otherwise, 0.

##### Author

klm127

##### Date

2/7/2023

#### 8.4.1.15 CompFiles\_promptInputFilename()

```
char * CompFiles_promptInputFilename ( )
```

Calls the function [getString\(\)](#) to receive a filename from the user and returns it. It will set the 'terminate requested' flag in CompFiles if the user inputs only a \n.

##### Returns

char \* inputfilename to be verified

##### Author

thomaserh99

##### Date

1/23/2023

##### Note

Covered by Unit Tests

#### 8.4.1.16 CompFiles\_promptOutputFilename()

```
char * CompFiles_promptOutputFilename ( )
```

Calls the function [getString\(\)](#) to receive a filename from the user and returns it. It will set the 'terminate requested' flag in CompFiles if the user inputs only a \n.

##### Warning

This should not be called until the input filename has been set. The user may elect to generate an output filename based on the input file. (inputfilename + .out)

**Returns**

A malloced string of an output filename to be verified.

**Author**

thomaserh99

**Date**

Created On: 1/23/2023

**Note**

Covered by Unit Tests

**8.4.1.17 CompFiles\_promptUserOverwriteSelection()**

```
short CompFiles_promptUserOverwriteSelection ( )
```

Prompts the user as to what they want to do about an output file already existing. It prints a prompt and parses the user response to one of the USER\_OUTPUT\_OVERWRITE\_SELECTION enums. It does NOT loop.

**Returns**

short corresponding to one of the enums of USER\_OTUPUT\_OVERWRITE\_SELECTION

**Author**

klm127, thomasterh99, anthony91501

**Date**

1/20/2023

**Note**

### 8.5.1 Detailed Description

CompFiles struct and "methods" definitions.

CompFiles struct and "methods".

CompFiles is a struct which holds pointers to the compilation input and output files. It also tracks their names and their validation status. It provides methods for prompting the user for valid file names until terminate is requested or all files are validated.

#### Authors

Tom Terhune, Karl Miller, Anthony Stepich

#### Date

January 2023

### 8.5.2 Enumeration Type Documentation

#### 8.5.2.1 COMPFILES\_STATE

enum [COMPFILES\\_STATE](#)

Describes the state of a filename validation process

#### Enumerator

<a href="#">COMPFILES_STATE_NO_NAME_PROVIDED</a>	
<a href="#">COMPFILES_STATE_NAME_NEEDS_VALIDATION</a>	
<a href="#">COMPFILES_STATE_NAME_VALIDATED</a>	

### 8.5.2.2 USER\_OUTPUT\_OVERWRITE\_SELECTION

enum `USER_OUTPUT_OVERWRITE_SELECTION`

Describes the possible selections a user may make when they elect to output to a file that already exists.

Enumerator

<code>USER_OUTPUT_OVERWRITE_REENTER_FILENAME_SELECTED</code>	
<code>USER_OUTPUT_OVERWRITE_OVERWRITE_EXISTING_FILE</code>	
<code>USER_OUTPUT_OVERWRITE_DEFAULT_FILENAME</code>	
<code>USER_OUTPUT_TERMINATE_PROGRAM</code>	
<code>USER_OUTPUT_TERMINATE_INVALID_ENTRY</code>	

## 8.5.3 Function Documentation

### 8.5.3.1 CompFiles\_AcquireValidatedFiles()

```
short CompFiles_AcquireValidatedFiles (
    char * inputFilename,
    const char * outputFilename )
```

Loops and prompts until all input and output files are set correctly or until terminate is requested. After the input, output, and listing files are generated, `CompFiles_AcquireValidatedFiles` also generates a temp file.

Parameters

<i>inputFilename</i>	a filename with which to begin input validation with or NULL
<i>outputFilename</i>	a filename with which to begin output validation with or NULL

Returns

1 if terminate was requested. Otherwise, 0.

Author

klm127

Date

1/26/2023

### 8.5.3.2 CompFiles\_AcquireValidatedInputFile()

```
short CompFiles_AcquireValidatedInputFile (
    char * filename )
```

Validates an input file name and sets the value in the struct. It will continue looping until the user has supplied a valid filename or elected to quit the program.

Parameters

<i>filename</i>	a filename with which to begin input validation with or NULL
-----------------	--

**Returns**

0 if the input file was validated and loaded into the struct. 1 if the user requested to terminate the program.

**8.5.3.3 CompFiles\_AcquireValidatedListingFile()**

```
short CompFiles_AcquireValidatedListingFile (
    const char * filename )
```

Validates a listing file name and sets the value in the struct.

Called by CompFiles\_ValidateOutputFile after an output file has been fully validated. The parameter passed will be the name of the output file with the extension 'list' instead.

If this file happens to exist, a similar loop will occur as when a user attempts to load an extant output file. The user will be prompted to enter a new file until one is validated or they elect to exit the program.

**Parameters**

<i>filename</i>	a filename with which to begin input validation with or NULL
-----------------	--

**Returns**

0 if an output file was validated and loaded into the struct. 1 if the user requested to terminate the program.

**8.5.3.4 CompFiles\_AcquireValidatedOutputFile()**

```
short CompFiles_AcquireValidatedOutputFile (
    const char * filename )
```

Validates an output file name and sets the value in the struct. It will continue looping until the user has supplied a valid filename or elected to quit the program.

**Parameters**

<i>filename</i>	a filename with which to begin input validation with or NULL
-----------------	--

**Returns**

0 if an output file was validated and loaded into the struct. 1 if the user requested to terminate the program.

**8.5.3.5 CompFiles\_CopyInputToOutputs()**

```
void CompFiles_CopyInputToOutputs ( )
```

CompFiles\_CopyInputToOutputs copies all the data from the input file to each of the output files. After execution, all output files (tmp, list, and out) will have text identical to the input files.

**Warning**

Precondition: All CompFiles file pointers must be open and ready to read/write.

**Author**

Thomas, Karl

**Date**

1/27/2023

### 8.5.3.6 CompFiles\_DeInit()

```
void CompFiles_DeInit ( )
```

Closes any open files and returns CompFiles to the default values. Deletes the temp file.

### 8.5.3.7 CompFiles\_GenerateTempFile()

```
void CompFiles_GenerateTempFile ( )
```

Generates a temporary file with a unique name. This file will be destroyed when [CompFiles\\_DeInit\(\)](#) is called.

#### Author

klm127

#### Date

1/26/2023

### 8.5.3.8 CompFiles\_GetFiles()

```
TCompFiles * CompFiles_GetFiles ( )
```

Gets the CompFiles struct so that the validated files can be used elsewhere in the program.

#### Returns

A [TCompFiles](#) struct.

### 8.5.3.9 CompFiles\_Init()

```
void CompFiles_Init ( )
```

Initializes CompFiles struct to default values.

#### Note

Covered by unit tests.

### 8.5.3.10 CompFiles\_LoadInputFile()

```
void CompFiles_LoadInputFile (
    FILE * newInputFile )
```

CompFiles\_LoadInputFile loads a new file pointer as the input file. If there is a file already loaded, it closes that file first.

#### Parameters

<i>newInputFile</i>	A pointer to an open file in read mode.
---------------------	---

### 8.5.3.11 CompFiles\_LoadListingFile()

```
void CompFiles_LoadListingFile (
    FILE * newListingFile )
```

CompFiles\_LoadListingFile loads a new file pointer as the listing file. If there is a file already loaded, it closes that file first.

## Parameters

<i>newOutputFile</i>	A pointer to an open file in write mode.
----------------------	--

**8.5.3.12 CompFiles\_LoadOutputFile()**

```
void CompFiles_LoadOutputFile (
    FILE * newOutputFile )
```

CompFiles\_LoadOutputFile loads a new file pointer as the output file. If there is a file already loaded, it closes that file first.

## Parameters

<i>newOutputFile</i>	A pointer to an open file in write mode.
----------------------	--

**8.5.3.13 CompFiles\_LoadTempFile()**

```
void CompFiles_LoadTempFile (
    FILE * newTempFile )
```

CompFiles\_LoadTempFile loads a new file pointer as the temp file. If there is a file already loaded, it closes that file first.

## Parameters

<i>newOutputFile</i>	A pointer to an open file in write mode.
----------------------	--

**8.5.3.14 CompFiles\_Open()**

```
short CompFiles_Open (
    int argc,
    char * argv[] )
```

Parses the command line args and calls functions to acquire validated filenames.

## Parameters

<i>argc</i>	The argument count.
<i>argv</i>	The argument array.

## Returns

1 if terminate was requested. Otherwise, 0.

## Author

klm127

## Date

2/7/2023

#### 8.5.3.15 CompFiles\_promptInputFilename()

```
char * CompFiles_promptInputFilename ( )
```

Calls the function [getString\(\)](#) to receive a filename from the user and returns it. It will set the 'terminate requested' flag in CompFiles if the user inputs only a \n.

##### Returns

char \* inputfilename to be verified

##### Author

thomaserh99

##### Date

1/23/2023

##### Note

Covered by Unit Tests

#### 8.5.3.16 CompFiles\_promptOutputFilename()

```
char * CompFiles_promptOutputFilename ( )
```

Calls the function [getString\(\)](#) to receive a filename from the user and returns it. It will set the 'terminate requested' flag in CompFiles if the user inputs only a \n.

##### Warning

This should not be called until the input filename has been set. The user may elect to generate an output filename based on the input file. (inputfilename + .out)

##### Returns

A malloced string of an output filename to be verified.

#### 8.5.3.17 CompFiles\_promptUserOverwriteSelection()

```
short CompFiles_promptUserOverwriteSelection ( )
```

Prompts the user as to what they want to do about an output file already existing. It prints a prompt and parses the user response to one of the USER\_OUTPUT\_OVERWRITE\_SELECTION enums. It does NOT loop.

##### Returns

short corresponding to one of the enums of USER\_OTUPUT\_OVERWRITE\_SELECTION

### 8.7.1 Detailed Description

The DFA and related logic definitions.

The DFA is a 3 dimensional array that maps a given state and character input to a result consisting of the next state, token, and whether reading should continue.

The DFA was created in Excel, and the excel file is available in docs/fullDFA.xlsx.

### 8.7.3 Function Documentation

#### 8.7.3.1 GetDFAColString()

```
char * GetDFAColString (
    int n )
```

GetDFAColString returns the column name associated with a given number. It is used only for debugging the DFA.

#### 8.7.3.2 GetDFAColumn()

```
short GetDFAColumn (
    char c )
```

Translates a given character into a column index of the state-transition table.

### 8.7.3.3 GetNextToken()

```
int GetNextToken (
    FILE * file,
    int * charsRead )
```

Gets the next token from the file. Skips leading whitespace. Sets charsRead to the number of characters read, not including whitespace skipped.

#### Parameters

<i>file</i>	A file to read for tokens.
<i>charsRead</i>	A pointer to an int. The value at charsRead will be overwritten with the number of chars read.

#### Returns

An int representing a token. See [tokens.c](#).

### 8.7.3.4 GetNextTokenInBuffer()

```
int GetNextTokenInBuffer (
    char * buffer,
    int * bufIndex,
    int * charsRead )
```

Gets the next token from a buffer. Skips leading whitespace. Sets charsRead to the number of characters read, not including whitespace skipped.

#### Note

This function primarily exists to test the DFA itself against buffers rather than passing in files.

#### Parameters

<i>buffer</i>	a character buffer
<i>bufIndex</i>	

### 8.7.3.5 GetStateString()

```
char * GetStateString (
    int n )
```

### 8.7.3.6 printCell()

```
void printCell (
    int row,
    int col )
```

A debug function for printing a cell in the DFA.

### 8.7.3.7 printStateAndChar()

```
void printStateAndChar (
    int row,
    int col )
```

A debug function for printing a state (row name) and column (char name)

## 8.7.4 Variable Documentation

### 8.7.4.1 DFA

```
short DFA[71][44][3]
```

The DFA drives the scanner logic. Each of the 71 rows in this state transition table corresponds to a state, or a node on a DFA graph.

Each column corresponds to an edge, with columns 0-25 being 'a' through 'z'. There are also operator characters. The ASCII code of a character is not its column position and characters must be converted to column numbers before they can index this state transition table. At each cell, there are three values. First is the next state to transition to. Second is the token. Third is a signal to the DFA driver whether to continue reading or not. It says, 'this character is a boundary character for this state'.

The DFA was generated in Excel, and that .xlsx file is available in the /docs folder of this project.

## 8.8 src/dfa.h File Reference

The DFA and related logic declarations.

```
#include <stdio.h>
```

### Functions

- short [GetDFAColumn](#) (char c)
- int [GetNextToken](#) (FILE \*file, int \*charsRead)
- int [GetNextTokenInBuffer](#) (char \*buffer, int \*bufIndex, int \*charsRead)
- void [printCell](#) (int row, int col)
- void [printStateAndChar](#) (int row, int col)

### 8.8.1 Detailed Description

The DFA and related logic declarations.

The DFA is a 3 dimensional array that maps a given state and character input to a result consisting of the next state, token, and whether reading should continue.

The DFA was created in Excel, and the excel file is available in docs/fullDFA.xlsx.

#### Authors

Tom Terhune, Karl Miller, Anthony Stepich

#### Date

February 2023

## 8.8.2 Function Documentation

### 8.8.2.1 GetDFAColumn()

```
short GetDFAColumn (
    char c )
```

Translates a given character into a column index of the state-transition table.

### 8.8.2.2 GetNextToken()

```
int GetNextToken (
    FILE * file,
    int * charsRead )
```

Gets the next token from the file. Skips leading whitespace. Sets charsRead to the number of characters read, not including whitespace skipped.

#### Parameters

<i>file</i>	A file to read for tokens.
<i>charsRead</i>	A pointer to an int. The value at charsRead will be overwritten with the number of chars read.

#### Returns

An int representing a token. See [tokens.c](#).

### 8.8.2.3 GetNextTokenInBuffer()

```
int GetNextTokenInBuffer (
    char * buffer,
    int * bufIndex,
    int * charsRead )
```

Gets the next token from a buffer. Skips leading whitespace. Sets charsRead to the number of characters read, not including whitespace skipped.

#### Note

This function primarily exists to test the DFA itself against buffers rather than passing in files.

#### Parameters

<i>buffer</i>	a character buffer
<i>bufIndex</i>	

### 8.8.2.4 printCell()

```
void printCell (
    int row,
    int col )
```

A debug function for printing a cell in the DFA.

### 8.8.2.5 printStateAndChar()

```
void printStateAndChar (
    int row,
    int col )
```

A debug function for printing a state (row name) and column (char name)

### Functions

- short [fileExists](#) (const char \*filename)
- void [backupFile](#) (const char \*filename)
- int [filenameHasExtension](#) (const char \*filename)
- char \* [addExtension](#) (const char \*filename, const char \*extension)
- char \* [removeExtension](#) (const char \*filename)
- char \* [generateAbsolutePath](#) (const char \*filename)
- short [checkIfSamePaths](#) (const char \*filename1, const char \*filename2)
- char \* [getString](#) ()

### 8.10.1 Function Documentation

#### 8.10.1.1 addExtension()

```

char * addExtension (
    const char * filename,
    const char * extension )

```

[addExtension](#) modifies the string given by `filename` by concatenating the string given by `extension`. [addExtension](#) returns a pointer to a new, concatenated string. This string is allocated with `malloc`. When you are done with it, the memory should be cleared with `free` to avoid memory leaks.

#### Parameters

<i>filename</i>	the char array to modify
<i>extension</i>	the char array to append

#### Authors

thomasterh99, klm127

#### Date

1/18/2023

**Note**

Covered by Unit Tests

**8.10.1.2 backupFile()**

```
void backupFile (
    const char * filename )
```

Renames an existing file, adding the extension '.bak' to the end of it. For example 'outFile.out' will become 'outFile.out.bak'.

If the backup file exists already, the new file will have additional '.bak's appended until a name is found that does not collide.

**Author**

klm127

**Date**

1/22/2023

**Note**

Covered by Unit Tests

**8.10.1.3 checkIfSamePaths()**

```
short checkIfSamePaths (
    const char * filename1,
    const char * filename2 )
```

checkIfSamePaths uses generateAbsolutePath to see if two filenames have the same resulting path.

**Precondition**

both filenames should be validated to be possible filenames.

**Parameters**

<i>filename1</i>	the first filename to check.
<i>filename2</i>	the second filename to check.

**Returns**

1 if they are the same path, 0 otherwise.

**Author**

karl

**Date**

2/1/2023

**8.10.1.4 fileExists()**

```
short fileExists (
    const char * filename )
```

fileExists checks whether a file with name filename exists.

**Parameters**

<i>filename</i>	: the filename to check.
-----------------	--------------------------

**Returns**

short:

- 1 if the file exists
- 0 if it does not.
- -1 if file cant exist

**Authors**

klm127

**Date**

1/19/2023

**Note**

Covered by Unit Tests

**8.10.1.5 filenameHasExtension()**

```
int filenameHasExtension (
    const char * filename )
```

filenameHasExtension checks whether a filename has an extension. It validates that a string would be a valid path but with one additional condition: it must have a period in the file name portion of the path followed by at least one character.

**Parameters**

<i>filename</i>	the string to check
-----------------	---------------------

**Returns**

int:

- the index of the . character in the string if it exists. otherwise, one of the negative FILE\_EXTENSION↔\_PARSE enums indicating why the filename is invalid;
  - (-1) means there was no period.
  - (-2) means it ended in a period.
  - (-3) means it is only a period.
  - (-4) means it ends in a slash and is a directory.

**Author**

klm127

**Date**

1/19/2023

**Note**

Covered by Unit Tests

#### 8.10.1.6 generateAbsolutePath()

```
char * generateAbsolutePath (
    const char * filename )
```

generateAbsolutePath uses a fileapi.h call to generate the absolute path for a given filename.

##### Precondition

filename has already been validated to have an extension

##### Parameters

<i>filename</i>	the filename to create an absolute path for
-----------------	---

##### Returns

a malloced string for a full path name

##### Warning

ensure the returned string is freed when you are done to avoid memory leaks

##### Authors

karl, anthony, thomas

##### Date

2/1/2023

#### 8.10.1.7 getString()

```
char * getString ( )
```

getString scans a string character by character until receiving a null termination character or a new line

##### Returns

a pointer to a new character array given by the user with a size of the number of characters + 4 for the possible extension This string is allocated with `malloc`. When you are done with it, the memory should be cleared with `free` to avoid memory leaks.

##### Author

thomaserh99

##### Date

1/23/2023

##### Note

Covered by Unit Tests

#### 8.10.1.8 removeExtension()

```
char * removeExtension (
    const char * filename )
```

removeExtension modifies the string given in parameters by copying the characters of the string up to the index of the last period.

##### Precondition

filename has been validated to have a correct extension (not leading with a '.', not ending with a '.')

#### Parameters

<i>filename</i>	the filename char* to remove the extension from.
-----------------	--

#### Returns

a pointer to a new, extensionless string.

#### Warning

This string is allocated with `malloc`. When you are done with it, the memory should be cleared with `free` to avoid memory leaks.

#### Authors

thomasterh99, klm127

#### Date

1/22/2023

#### 8.11.2 Enumeration Type Documentation

### 8.11.2.1 FILE\_EXISTS\_ENUM

enum `FILE_EXISTS_ENUM`

Alias for true false, 1, 0

#### Enumerator

<code>FILE_CANT_EXIST</code>	
<code>FILE_EXISTS</code>	
<code>FILE_DOES_NOT_EXIST</code>	

### 8.11.2.2 FILENAME\_EXTENSION\_PARSE

enum `FILENAME_EXTENSION_PARSE`

The enum `FILENAME_EXTENSION_PARSE` describes possible return values from `filenameHasExtension` which indicate different ways which a filename may be invalid.

#### Enumerator

<code>FILENAME_HAS_NO_PERIOD</code>	
<code>FILENAME_ENDS_IN_PERIOD</code>	
<code>FILENAME_IS_ONLY_PERIOD</code>	
<code>FILENAME_IS_DIRECTORY</code>	

## 8.11.3 Function Documentation

### 8.11.3.1 addExtension()

```
char * addExtension (
    const char * filename,
    const char * extension )
```

`addExtension` modifies the string given by `filename` by concatenating the string given by `extension`.

`addExtension` returns a pointer to a new, concatenated string. This string is allocated with `malloc`. When you are done with it, the memory should be cleared with `free` to avoid memory leaks.

#### Parameters

<i>filename</i>	the char array to modify
<i>extension</i>	the char array to append

#### Authors

thomasterh99, klm127

#### Date

1/18/2023

#### Note

Covered by Unit Tests

### 8.11.3.2 backupFile()

```
void backupFile (
    const char * filename )
```

Renames an existing file, adding the extension '.bak' to the end of it. For example 'outFile.out' will become 'outFile.out.bak'.

If the backup file exists already, the new file will have additional '.bak's appended until a name is found that does not collide.

#### Note

Covered by Unit Tests

### 8.11.3.3 checkIfSamePaths()

```
short checkIfSamePaths (
    const char * filename1,
    const char * filename2 )
```

checkIfSamePaths uses generateAbsolutePath to see if two filenames have the same resulting path.

#### Precondition

both filenames should be validated to be possible filenames.

#### Parameters

<i>filename1</i>	the first filename to check.
<i>filename2</i>	the second filename to check.

#### Returns

1 if they are the same path, 0 otherwise.

#### Author

karl

#### Date

2/1/2023

### 8.11.3.4 fileExists()

```
short fileExists (
    const char * filename )
```

fileExists checks whether a file with name filename exists.

#### Parameters

<i>filename</i>	: the filename to check.
-----------------	--------------------------

**Returns**

short:

- 1 if the file exists
- 0 if it does not.
- -1 if file cant exist

**Authors**

klm127

**Date**

1/19/2023

**Note**

Covered by Unit Tests

**8.11.3.5 filenameHasExtension()**

```
int filenameHasExtension (
    const char * filename )
```

filenameHasExtension checks whether a filename has an extension. It validates that a string would be a valid path but with one additional condition: it must have a period in the file name portion of the path followed by at least one character.

**Parameters**

<i>filename</i>	the string to check
-----------------	---------------------

**Returns**

int:

- the index of the . character in the string if it exists. otherwise, one of the negative `FILE_EXTENSION↵_PARSE` enums indicating why the filename is invalid;
  - (-1) means there was no period.
  - (-2) means it ended in a period.
  - (-3) means it is only a period.
  - (-4) means it ends in a slash and is a directory.

**Author**

klm127

**Date**

1/19/2023

**Note**

Covered by Unit Tests

### 8.11.3.6 generateAbsolutePath()

```
char * generateAbsolutePath (
    const char * filename )
```

generateAbsolutePath uses a fileapi.h call to generate the absolute path for a given filename.

#### Precondition

filename has already been validated to have an extension

#### Parameters

<i>filename</i>	the filename to create an absolute path for
-----------------	---

#### Returns

a malloced string for a full path name

#### Warning

ensure the returned string is freed when you are done to avoid memory leaks

#### Authors

karl, anthony, thomas

#### Date

2/1/2023

### 8.11.3.7 getString()

```
char * getString ( )
```

getString scans a string character by character until receiving a null termination character or a new line

#### Returns

a pointer to a new character array given by the user with a size of the number of characters + 4 for the possible extension This string is allocated with `malloc`. When you are done with it, the memory should be cleared with `free` to avoid memory leaks.

#### Author

thomaserh99

#### Date

1/23/2023

#### Note

Covered by Unit Tests

### 8.11.3.8 removeExtension()

```
char * removeExtension (
    const char * filename )
```

removeExtension modifies the string given in parameters by copying the characters of the string up to the index of the last period.

#### Precondition

filename has been validated to have a correct extension (not leading with a '.', not ending with a '.')

**Parameters**

<i>filename</i>	the filename char* to remove the extension from.
-----------------	--

**Returns**

a pointer to a new, extensionless string.

**Warning**

This string is allocated with `malloc`. When you are done with it, the memory should be cleared with `free` to avoid memory leaks.

**Authors**

thomasterh99, klm127

**Date**

1/22/2023

## 8.14.2 Enumeration Type Documentation

### 8.14.2.1 LHEAD\_RESULT

enum [LHEAD\\_RESULT](#)

Enumerator

LH_CLEAR	
LH_NLINE	
LH_EOF	
LH_COMMENT	

## 8.14.3 Function Documentation

### 8.14.3.1 Scanner\_AdvanceLine()

void Scanner\_AdvanceLine ( )

Advances the file pointer until the start of the next line. Increments the line-number counter in scanner.

### 8.14.3.2 Scanner\_BackprintIdentifier()

void Scanner\_BackprintIdentifier (   
int *nchars* )

Moves the file pointer of scanner.in back *nchars* and prints that many chars to the output file and possibly the console. Used for printing the actual text of a token.

Parameters

<i>nchars</i>	The number of characters to backprint.
---------------	--

### 8.14.3.3 Scanner\_bufputc()

void Scanner\_bufputc (   
char *c* )

Puts a character in the buffer. Increments scanner.l\_buffer. Calls `expandBuffer()` if necessary.

### 8.14.3.4 Scanner\_clearBuffer()

void Scanner\_clearBuffer ( )

If scanner.buffer has been allocated, it is freed. `Scanner.buffer` is given memory on the heap equal to the const `SCANNER_BUFFER_INITIAL_CAPACITY`.

Also resets scanner.l\_buffer to 0 and scanner.capacity.

### 8.14.3.5 Scanner\_DeInit()

void Scanner\_DeInit ( )

De-initializes scanner values, setting file pointers to NULL (but not closing files. )

### 8.14.3.6 Scanner\_expandBuffer()

void Scanner\_expandBuffer ( )

Doubles the size of the buffer, preserving data in the buffer (But possibly moving it to a different location). `Scanner.buffer` will point to a buffer twice as large and `scanner.capacity` will be doubled. If necessary, an old buffer may have been freed. Do not use scanner's buffer directly as it may be freed; copy the string to a new buffer when extraction is necessary.

#### 8.14.3.7 `Scanner_Init()`

```
void Scanner_Init ( )
```

Initializes scanner values to zero.

#### 8.14.3.8 `Scanner_Lookahead()`

```
short Scanner_Lookahead ( )
```

Looks ahead to determine if there are any more tokens on the line, or if there is a comment at the end of the line. Resets the fileposition after looking ahead.

Returns

0 = Clear to Scan, 1 = Newline next, 2 = EOF next, 3 = Comment next,

#### 8.14.3.9 `Scanner_PrintBufferToOutputFile()`

```
void Scanner_PrintBufferToOutputFile ( )
```

Prints the buffer to the output file, expecting a null-terminated string. Also prints it to the console if console printing is enabled.

#### 8.14.3.10 `Scanner_PrintErrorListing()`

```
void Scanner_PrintErrorListing ( )
```

Prints an error message to the listing file and possibly the console. Example: `\nError. & not recognized.`

#### 8.14.3.11 `Scanner_PrintErrorSummary()`

```
void Scanner_PrintErrorSummary ( )
```

Prints the total error count to the listing file and possibly the console.

#### 8.14.3.12 `Scanner_PrintLine()`

```
void Scanner_PrintLine ( )
```

Prints a line with a line number to the listing file. Will print newlines but will not print EOFs. Resets the file pointer to its original position after printing the line.

#### 8.14.3.13 `Scanner_PrintTokenFront()`

```
void Scanner_PrintTokenFront (
    int token )
```

#### 8.14.3.14 `Scanner_ReadBackToBuffer()`

```
void Scanner_ReadBackToBuffer (
    int n_chars )
```

Reads back a number of characters from `scanner.in` into the buffer. The file pointer will be in the same position after execution.

### 8.14.3.15 Scanner\_ScanAndPrint()

```
void Scanner_ScanAndPrint (
    FILE * input,
    FILE * listing,
    FILE * output,
    FILE * temp )
```

Scans a file for tokens and prints detailed information to the listing and output files.

#### Parameters

<i>input</i>	An input file pointer, already opened for reading.
<i>listing</i>	An listing file pointer, already opened for writing.
<i>output</i>	An output file pointer, already opened for writing.
<i>temp</i>	An temp file pointer, already opened for writing.

### 8.14.3.16 Scanner\_SkipWhitespace()

```
int Scanner_SkipWhitespace ( )
```

Advances the file pointer until a nonwhitespace character (not space or tab) and returns the number of characters skipped.

While the DFA can skip whitespace independently, using this method allows tracking the number of characters that were skipped to maintain an accurate column number.

#### Returns

The number of whitespace characters skipped.

## 8.14.4 Variable Documentation

### 8.14.4.1 scanner

```
struct Scanner scanner
```

```
#define SCANNER_PRINTS_TOKENS_TO_CONSOLE 1
```

### 8.15.3 Function Documentation

#### 8.15.3.1 Scanner\_AdvanceLine()

```
void Scanner_AdvanceLine ( )
```

Advances the file pointer until the start of the next line. Increments the line-number counter in scanner.

### 8.15.3.2 Scanner\_BackprintIdentifier()

```
void Scanner_BackprintIdentifier (  
    int nchars )
```

Moves the file pointer of scanner.in back *nchars* and prints that many chars to the output file and possibly the console. Used for printing the actual text of a token.

## Parameters

<i>nchars</i>	The number of characters to backprint.
---------------	--

**8.15.3.3 Scanner\_bufputc()**

```
void Scanner_bufputc (
    char c )
```

Puts a character in the buffer. Increments scanner.l\_buffer. Calls expandBuffer() if necessary.

**8.15.3.4 Scanner\_clearBuffer()**

```
void Scanner_clearBuffer ( )
```

If scanner.buffer has been allocated, it is freed. [Scanner.buffer](#) is given memory on the heap equal to the const `SCANNER_BUFFER_INITIAL_CAPACITY`.

Also resets scanner.l\_buffer to 0 and scanner.capacity.

**8.15.3.5 Scanner\_DeInit()**

```
void Scanner_DeInit ( )
```

De-initializes scanner values, setting file pointers to NULL (but not closing files. )

**8.15.3.6 Scanner\_expandBuffer()**

```
void Scanner_expandBuffer ( )
```

Doubles the size of the buffer, preserving data in the buffer (But possibly moving it to a different location). [Scanner.buffer](#) will point to a buffer twice as large and scanner.capacity will be doubled. If necessary, an old buffer may have been freed. Do not use scanner's buffer directly as it may be freed; copy the string to a new buffer when extraction is necessary.

**8.15.3.7 Scanner\_Init()**

```
void Scanner_Init ( )
```

Initializes scanner values to zero.

**8.15.3.8 Scanner\_Lookahead()**

```
short Scanner_Lookahead ( )
```

Looks ahead to determine if there are any more tokens on the line, or if there is a comment at the end of the line. Resets the fileposition after looking ahead.

## Returns

0 = Clear to Scan, 1 = Newline next, 2 = EOF next, 3 = Comment next,

**8.15.3.9 Scanner\_PrintBufferToOutputFile()**

```
void Scanner_PrintBufferToOutputFile ( )
```

Prints the buffer to the output file, expecting a null-terminated string. Also prints it to the console if console printing is enabled.

**8.15.3.10 Scanner\_PrintErrorListing()**

```
void Scanner_PrintErrorListing ( )
```

Prints an error message to the listing file and possibly the console. Example: `\nError. & not recognized.`

**8.15.3.11 Scanner\_PrintErrorSummary()**

```
void Scanner_PrintErrorSummary ( )
```

Prints the total error count to the listing file and possibly the console.

**8.15.3.12 Scanner\_PrintLine()**

```
void Scanner_PrintLine ( )
```

Prints a line with a line number to the listing file. Will print newlines but will not print EOFs. Resets the file pointer to its original position after printing the line.

**8.15.3.13 Scanner\_PrintTokenFront()**

```
void Scanner_PrintTokenFront ( )
```

Prints the token output to the output file and possibly the console. Example: \ntoken number: 0 token type: BEGIN  
actual token: After calling, Scanner\_BackprintIdentifier should be called to print the actual token.

**8.15.3.14 Scanner\_ReadBackToBuffer()**

```
void Scanner_ReadBackToBuffer (
    int n_chars )
```

Reads back a number of characters from scanner.in into the buffer. The file pointer will be in the same position after execution.

**8.15.3.15 Scanner\_ScanAndPrint()**

```
void Scanner_ScanAndPrint (
    FILE * input,
    FILE * listing,
    FILE * output,
    FILE * temp )
```

Scans a file for tokens and prints detailed information to the listing and output files.

**Parameters**

<i>input</i>	An input file pointer, already opened for reading.
<i>listing</i>	An listing file pointer, already opened for writing.
<i>output</i>	An output file pointer, already opened for writing.
<i>temp</i>	An temp file pointer, already opened for writing.

**8.15.3.16 Scanner\_SkipWhitespace()**

```
int Scanner_SkipWhitespace ( )
```

Advances the file pointer until a nonwhitespace character (not space or tab) and returns the number of characters skipped.

While the DFA can skip whitespace independently, using this method allows tracking the number of characters that were skipped to maintain an accurate column number.

**Returns**

The number of whitespace characters skipped.

- void [Token\\_Destroy](#) (struct [TokenCatch](#) \*token)

### Variables

- const char \* [tokensMap](#) []

#### 8.19.1 Detailed Description

Token map and related functions.

The tokensMap maps a given token to a constant string, which is used by [Token\\_GetName\(\)](#) to get the name of a token. The index of a token string in the tokensMap is the same as it's enumerated value. E.G, BEGIN is value 0 and "BEGIN" is at position 0 in the tokensMap array.

This file also contains definitions for [TokenCatch](#) methods, which are no longer used. In an earlier version of the program, a [TokenCatch](#) wrapped a given token with related data and was memory-allocated. The current version does not use [TokenCatch](#), but it is retained here in case we need it for future parsing features.

#### Authors

Tom Terhune, Karl Miller, Anthony Stepich

#### Date

February 2023

#### 8.19.2 Function Documentation

### 8.19.2.1 Token\_Catch()

---

```
struct TokenCatch * Token_Catch (
    short tokenType,
    char * raw_text_found,
    int line_found_at,
    int col_found_at )
```

---

**8.19.2.2 Note:** [TokenCatch](#) is no longer used. It was used in an earlier version of this program. It may be revived in the future depending on the needs of the parser.

### 8.19.2.3 Token\_CatchError()

```
struct TokenCatch * Token_CatchError (
    char badChar,
    int line_found_at,
    int col_found_at )
```

[Token\\_CatchError](#) is called when an error is found. Whatever character is passed in will become the 'raw' member of a [TokenCatch](#).

#### Parameters

<i>tokenType</i>	A type in enum <code>TOKEN</code>
<i>raw_text_found</i>	A char pointer to the raw text that caused this token to be identified as such.
<i>line_found_at</i>	The line in the file the token was found.
<i>col_found_at</i>	The column at which the token was found.

#### Returns

A pointer to a malloced [TokenCatch](#) encapsulating the parameter data.

### 8.19.2.4 Token\_CatchOp()

```
struct TokenCatch * Token_CatchOp (
    short tokenType,
    int line_found_at,
    int col_found_at )
```

[Token\\_CatchOp](#) is called when an op is found. It still produces a [TokenCatch](#) but it infers the text that was found based on the token type rather than needing the raw text, since there is not variation in how the operators can be written.

#### Parameters

<i>tokenType</i>	A type in enum <code>TOKEN</code>
<i>raw_text_found</i>	A char pointer to the raw text that caused this token to be identified as such.
<i>line_found_at</i>	The line in the file the token was found.
<i>col_found_at</i>	The column at which the token was found.

#### Returns

A new [TokenCatch](#) encapsulating the parameter data.

### 8.19.2.5 Token\_Destroy()

```
void Token_Destroy (
    struct TokenCatch * token )
```

Token\_Destroy deallocates a token by first freeing the internal 'raw' string, then deallocating the token itself.

#### Parameters

<i>token</i>	A token to deallocate.
--------------	------------------------

### 8.19.2.6 Token\_GetName()

```
const char * Token_GetName (
    int id )
```

Token\_GetName gets a character string representing a token.

#### Parameters

<i>id</i>	The token ENUM to retrieve.
-----------	-----------------------------

#### Returns

const char\* A string from a lookup table, e.g, "BEGIN". If the param is not a valid token, then it returns "NULL".

#### Author

klm127

#### Date

2/7/2023

#### Note

Covered By Unit Tests

### 8.19.2.7 Token\_GetOpRaw()

```
char * Token_GetOpRaw (
    short tokenType )
```

Token\_GetOpRaw gets a malloced string for assignment to raw representing what must have been found for an operator text given an enumerated operator token. If its not one of the operators, it returns ':', which is the one case when a valid operator character was a syntactic error.

#### Parameters

<i>tokenType</i>	The operator token enumerated id
------------------	----------------------------------

#### Returns

A malloced string containing the operator, e.g. "<=".

## 8.19.3 Variable Documentation

### 8.19.3.1 tokensMap

```
const char* tokensMap[]
```

TokensMap maps each token to the corresponding string.

#### Warning

If you change the order in the enum, you must also change the order in this map!

## 8.20 src/tokens.h File Reference

Token functions declarations.

```
#include <stdlib.h>
```

## 8.20.3 Function Documentation

### 8.20.3.1 Token\_Catch()

```
struct TokenCatch * Token_Catch (
    short tokenType,
    char * raw_text_found,
    int line_found_at,
    int col_found_at )
```

Token\_Catch is called when an actual token has been found. It produces a [TokenCatch](#) struct which wraps the token type with other associated data, such as the raw text that was found and the line it was found at.

#### Parameters

<i>tokenType</i>	A type in enum TOKEN
<i>raw_text_found</i>	A char pointer to the raw text that caused this token to be identified as such.
<i>line_found_at</i>	The line in the file the token was found.
<i>col_found_at</i>	The column at which the token was found.

#### Returns

A new [TokenCatch](#) encapsulating the parameter data.

**8.20.3.2 Note: TokenCatch is no longer used. It was used in an earlier version of this program. It may be revived in the future depending on the needs of the parser.**

#### 8.20.3.3 Token\_CatchError()

```
struct TokenCatch * Token_CatchError (
    char badChar,
    int line_found_at,
    int col_found_at )
```

Token\_CatchError is called when an error is found. Whatever character is passed in will become the 'raw' member of a [TokenCatch](#).

#### Parameters

<i>tokenType</i>	A type in enum TOKEN
<i>raw_text_found</i>	A char pointer to the raw text that caused this token to be identified as such.
<i>line_found_at</i>	The line in the file the token was found.
<i>col_found_at</i>	The column at which the token was found.

#### Returns

A pointer to a malloced [TokenCatch](#) encapsulating the parameter data.

#### 8.20.3.4 Token\_CatchOp()

```
struct TokenCatch * Token_CatchOp (
    short tokenType,
    int line_found_at,
    int col_found_at )
```

Token\_Catch\_Op is called when an op is found. It still produces a [TokenCatch](#) but it infers the text that was found based on the token type rather than needing the raw text, since there is not variation in how the operators can be written.

#### Parameters

<i>tokenType</i>	A type in enum TOKEN
<i>raw_text_found</i>	A char pointer to the raw text that caused this token to be identified as such.
<i>line_found_at</i>	The line in the file the token was found.
<i>col_found_at</i>	The column at which the token was found.

**Returns**

A new [TokenCatch](#) encapsulating the parameter data.

**8.20.3.5 Token\_Destroy()**

```
void Token_Destroy (
    struct TokenCatch * token )
```

Token\_Destroy deallocates a token by first freeing the internal 'raw' string, then deallocating the token itself.

**Parameters**

<i>token</i>	A token to deallocate.
--------------	------------------------

**8.20.3.6 Token\_GetName()**

```
const char * Token_GetName (
    int id )
```

Token\_GetName gets a character string representing a token.

**Parameters**

<i>id</i>	The token ENUM to retrieve.
-----------	-----------------------------

**Returns**

const char\* A string from a lookup table, e.g, "BEGIN". If the param is not a valid token, then it returns "NULL".

**Author**

klm127

**Date**

2/7/2023

**Note**

Covered By Unit Tests

**8.20.3.7 Token\_GetOpRaw()**

```
char * Token_GetOpRaw (
    short tokenType )
```

Token\_GetOpName gets a malloced string for assignment to raw representing what must have been found for an operator text given an enumerated operator token. If its not one of the operators, it returns '.', which is the one case when a valid operator character was a syntactic error.

**Parameters**

<i>tokenType</i>	The operator token enumerated id
------------------	----------------------------------

**Returns**

A malloced string containing the operator, e.g. "<=".

## 8.22.1 Function Documentation

### 8.22.1.1 Enable\_PrettyPrint()

```
void Enable_PrettyPrint ( )
```

Enables pretty printing. (Virtual Terminal Sequences)

### 8.22.1.2 Tompiler\_DeInit()

```
void Tompiler_DeInit ( )
```

Tompiler\_DeInit deinitializes Tompiler modules.

### 8.22.1.3 Tompiler\_Execute()

```
void Tompiler_Execute (
    int argc,
    char * argv[] )
```

Tompiler\_Execute with command line args

### 8.22.1.4 Tompiler\_Goodbye()

```
void Tompiler_Goodbye ( )
```

Prints the goodbye message.

### 8.22.1.5 Tompiler\_Hello()

```
void Tompiler_Hello ( )
```

Prints the hello message.

### 8.22.1.6 Tompiler\_Init()

```
void Tompiler_Init ( )
```

Tompiler\_Init the program by initializing the modules needed by Tompiler modules in the correct order.

## 8.22.2 Variable Documentation

### 8.22.2.1 handle

```
HANDLE handle
```

## 8.23 src/tompiler.h File Reference
